**TREATMENT OF UROLOGICAL AND GASTRIC FLUID REFLUX  
DISORDERS BY INJECTION OF MICRO PARTICLES**

**CROSS-REFERENCE TO RELATED APPLICATION**

Cross reference is made to a related application of common inventorship and assignee, Serial No. 07/714,273, filed June 12, 1991<sup>now US. patent No. 5,258,028</sup> which in turn is a continuation-in-part of Serial No. 07/282,671, filed December 12, 1988<sup>now abandoned</sup>

**BACKGROUND OF THE INVENTION**

**I. Field of the Invention**

This invention is directed generally to the permanent augmentation of soft tissue and, more particularly, to the treatment of urological disorders, e.g., incontinence, vesicoureteral reflux, gastric fluid reflux, etc., by endoscopic injection of compatible micro particle implants into the submucosal tissue. Since the invention is closely related to the treatment of incontinence, it will be described in detail by reference thereto.

With the exception of urinary incontinence secondary to neurogenic disorders, incontinence occurs when the resistance to urine flow has decreased excessively, i.e., urethral resistance to urine outflow, from whatever cause, has been lowered to the point when it can no longer resist increased intra-abdominal pressure. While this may seem to be an oversimplification of the problem, in general nearly all procedures developed to restore continence are designed on this basis to restore the lost resistance to urine outflow. Similarly, the present invention allows for the control

of gastric fluid reflux when submucosal injections of the micro implants are made to the esophageal-gastric junction and to the gastric-pyloric junction.

To these ends, several surgical procedures and devices have heretofore been developed and tried with varying degrees of success, e.g., suspension procedures, plications, constrictive procedures and various combinations of these. Devices which have been developed primarily operate as plugs and cannot be used on a permanent basis. Electrical stimulation and biofeedback techniques have so far been demonstrated to have limited success in treatment of incontinence and gastric reflux.

## II. Discussion of the Related Art

As examples of such treatments and procedures heretofore known in the art, mention may be made of a variety of prosthetic devices based on the compression of the urethra at a given point. (See, for example, "Treatment of urinary incontinence by implantable prosthetic sphincter," by Bradley and Timm, Urology, 1:252 (1973); "Treatment of post-prostatectomy urinary incontinence using a gel prostheses", by Kaufman, Brit. J. Urol., 45:646 (1973) and "Treatment of post-prostatectomy urinary incontinence using a silicon gel prostheses", Brit. J. Urol., 48:646 (1973).

In the practice of plastic and reconstructive surgery, inert materials have frequently been implanted to fill in defects or augment weakened tissue. These have been fabricated of a variety of materials and have been implanted using several techniques.

Certain very small particle species compounded in a lubricious material have been implanted by subcutaneous injection for both soft and hard tissue augmentation. Heretofore success has been limited. Undesirable subsequent particle migration and serious granulomatous reactions have commonly resulted. This is well documented with such materials as polytetrafluoroethylene (PTFE) particles of very small diameter (>90% of a diameter <30 microns) in glycerine. One such product includes PTFE particles, suspended in glycerine with a minor amount of polysorbate is available under the name Polytef® (trademark of Mentor Corp. of California). This is discussed, for example, in Malizia, et al., JAMA, Volume 251, No. 24, pp. 3277-3281 (1984).

U.S. Patent No. 4 773 393 issued September 27, 1988 to Haber and Malizia and assigned to C.R. Bard, Inc. relates to an apparatus for hypodermically implanting a genitourinary prosthesis comprising an extensible, inflatable tissue expanding containment membrane to be located in the proximal periurethral tissues to add bulk to these tissues and thereby overcome urinary incontinence by means of localized, controlled tissue volume increase. In column 1, reference is made to the aforementioned JAMA article co-authored by the co-patentee Anthony A. Malizia with respect to the widespread migration of polytef particles along with granulomas. Accordingly, the patented invention is said to obviate these problems by providing a prosthesis comprising an elastomeric biocompatible containment membrane into which a biomeric fluid or suspended

particulate matter such as TEFLON particles is percutaneously injected to inflate the membrane.

B14  
LL5  
F  
LB  
10 The use of very small diameter particulate spheres (approximately 1-20 microns) or small diameter elongated fibrils, (generally 1-20 microns in diameter) of various materials such as cross-linked collagen or synthetic polymers suspended in an aqueous medium to which a biocompatible fluid lubricant has been added as injectable implant composition is disclosed in Wallace et al., U.S. Patent 4 803 075. While these materials create immediate augmentation, this result is generally short-lived as the material also has a tendency to migrate and/or be reabsorbed from the injection site by the host tissue.

15 Most recently, three companies have indicated in published reports their intent to enter the market for treatment of urinary incontinence with an injectable material. Mentor Corporation has received limited approval from the FDA for use of their injectable material, "Urethrin", in treating incontinent male post-prostatectomy patients. Previous published reports stated that C.R. Bard, Inc. and Collagen Corporation were developing an  
20 incontinence treatment called "Contigen Bard Collagen Implant," understood to be Collagen Corporation's "contigen" injectable bovine collagen material. Subsequently, it was reported that C.R. Bard is also evaluating for urinary incontinence treatment a product called "Hylagel-Muscle" which is said to be based upon  
25 Biomatrix's patented technology on modifying naturally occurring

hyaluronan "to form three-dimensional sponge-like matrixes in the form of high molecular mass fluids, gels and solids that can separate tissue, cells and molecules."

From the foregoing survey of the current state of the art, it will thus been seen that of recent date many approaches and treatments have been proposed to cure or relieve conditions of urinary incontinence by injection. While some of these approaches have enjoyed modest success, relief has been, for the most part, only temporary in those patients where success is noted. This generally is due to granuloma reactions and/or migration of injected particulate material and reabsorption of gellular materials. Thus, there remains a very important need for a treatment that will provide a lasting remedy for successfully treating such urological disorders.

#### SUMMARY OF THE INVENTION

The present invention provides an improved method for treating urological disorders such as stress incontinence and gastric fluid reflux disorders, by injecting endoscopically a biocompatible fluid vehicle containing non-absorbable polymeric, particulate micro-implants which are characterized as being biocompatible, immunologically non-reactive and which will take advantage of the body's own mechanism to encapsulate the micro-implanted particles to prevent migration from the injection site. In accordance with the present invention, the aforementioned tasks are solved in an elegant manner by the endoscopic injection of regularly or

irregularly shaped, textured or relatively smooth micro particles combined with a biocompatible fluid vehicle.

BQ  
5  
B  
B621  
10  
The textured micro particles have a nominal unidimensional measurement of between about 30 and 3000 microns (.003 to 3.0 mm), and a preferred range for most applications is between about 80 and 600 microns (0.008 to 0.6 mm). The textured micro particles present generally amorphous surfaces, and normally possess surface irregularities including indentations ranging in size from, for example, 10Å (angstroms) to 500 microns, with the indentations themselves having irregular configurations and surfaces. A minimal inter-indentation distance is maintained that enables the particles to be injected through an hypodermic needle of the appropriate preselected size, and with or without a physiologic vehicle.

15  
20  
25  
Examples of appropriate physiologic vehicles are saline, solutions of sodium hyaluronate, various starches, hydrogels, polyvinylpyrrolidones, other polymeric materials, polysaccharides, organic oils or fluids, all of which are well known and utilized in the art. Vehicles that are biologically compatible, i.e., cause minimal tissue reaction and are removed or metabolized without cytotoxicity, are, of course, preferred. Biologically compatible saccharides such as glucose have been found useful, aqueous solutions of starch or sodium hyaluronate may be employed and certain fats may also be found useful. In certain instances, it may be desirable to employ a totally inert vehicle. The patient's own plasma may be derived from blood withdrawn from the patient,

centrifuged to remove cells (or not) and mixed with appropriate aliquots of particles and the mixture injected in the desired locations.

H, B, 14  
198

In this connection, highly compatible vehicles include esters of hyaluronic acids such as ethyl hyaluronate and polyvinylpyrrolidone (PVP). PVP normally has the general empirical formula  $[(CHCH_2)_2N(CH_2)_3CO]_n$  wherein n equals 25-500, a form of which is otherwise known and marketed as Plasdone™ (trademark of GAF Corporation, New York, New York). Additionally, polyvinylpyrrolidone (Plasdone), hyaluronate, collagen and other biocompatible substances may be incorporated into the elastomer or combined with its surface.

In certain instances, it has been found desirable to utilize a surface modifier in combination with the micro particles, with materials such as polyvinylpyrrolidone, polytetrafluoroethylene, collagen, or hyaluronates having been found suitable. In this connection, the surface modifiers may be mixed into the substance of or with the micro particles, and furthermore may thereafter be coated with a layer of a hyaluronate or hyaluronic acid. Specifically, certain modifiers such as polytetrafluoroethylene may be admixed with, for example, a poly di-substituted siloxane particle material prior to cure to impart an average surface modification to the cured particle. A material such as hyaluronic acid may be attached to the micro particle surface either through physical or chemical bonding. Surface modifiers also can be used

to typically assist in detoxification and promote the desired tissue ingrowth encapsulation. Other bioactive substances that can be included in the carrier or attached to the surface of the beads to promote encapsulation include fibronectin, n, transforming growth factor beta, and various other cytokines such as interleukin-1.

#### BRIEF DESCRIPTION OF THE DRAWINGS

**DETAILED DESCRIPTION**

As heretofore mentioned, the present invention is directed to the treatment of urological and gastric fluid reflux disorders, particularly stress incontinence, by endoscopic injection of specified micro particles. The above-referenced copending application relates to an improved micro-implantation method and composition for filling depressed scars, unsymmetrical orbital floors, muscle, lip, and other tissue defects in reconstructive surgery procedures. The tissues to be augmented exhibit varying degrees of softness.

B  
As disclosed, textured micro particles having an outside diameter between about 30 microns and 3000 microns are employed with an appropriate physiologic vehicle, as will be detailed hereinafter. A more preferred range is above about 80 microns and depending on the precise application between about 80 to 100 and 600 microns. Equivalent smooth particles should be somewhat larger.

In accordance with the invention, the particles are preferably injected through a hypodermic needle of an appropriate preselected size, preferably with an appropriate lubricious physiologic vehicle

which is biocompatible, i.e. causes minimal tissue reaction and is removed or metabolized without cytotoxicity. As indicated above, and by way of illustration, possible suitable useful disclosed physiologic vehicles include, saline, various starches, hydrogels, polyvinylpyrrolidones (Plasdone), polysaccharides, fats, organic oils or fluids and other polymeric materials, all of which are well known and utilized in the art. In this connection, highly compatible vehicles also include esters of hyaluronic acids such as ethyl hyaluronate and polyvinylpyrrolidone (PVP). PVP normally has the general empirical formula  $[(CHCH_2)_2N(CH_2)_3CO]_n$  wherein n is in the range of about 25-500, a form of which is otherwise known and marketed as Plasdone™, or the patient's own plasma.

Additionally, polyvinylpyrrolidone (Plasdone), hyaluronate, collagen and other biocompatible substances may be incorporated into the elastomer or combined with its surface. As used herein, a "surface modifier" connotes a material combined into the formed particle, applied to the surface of the particle or added to the carrier vehicle to alter inter-particle or prosthesis-host interaction and/or particle identifiability. These surface modifiers may alter the coefficient of friction of the particles, as by making them more lubricious, render the particles more radiopaque, assist in detoxification, and/or render the surface of the particles more susceptible to tissue ingrowth or facilitate tissue encapsulation of individual particles. Useful surface

modifiers include PVP, collagen, hyaluronates, polytetrafluoroethylene, and others.

5 The surface modifiers such as polyvinylpyrrolidone or polytetrafluoroethylene may be mixed into the substance of or with the micro particles, which furthermore may thereafter be coated with a layer of a hyaluronate or hyaluronic acid. Specifically, certain modifiers such as polytetrafluoroethylene may be admixed with, for example, a poly di-substituted siloxane particle material prior to cure to impart an average surface modification to the cured particle. A material such as hyaluronic acid may be attached to the micro particle surface either thorough physical or chemical bonding. Surface modifiers also typically are selected to assist in detoxification and promote the desired tissue encapsulation. As mentioned above, other bioactive substances that can be included in the carrier or attached to the surface of the micro implants to promote encapsulation include fibronectin, n, transforming growth factor beta, and various other cytokines such as interleukin-1.

10 Once implanted, the body will form a thin scar tissue around each of the implants so as to provide initial encapsulation. Polyvinylpyrrolidone, hyaluronate or collagen or other biocompatible substances may be chemically or physically combined with the particle substance or its surface to enhance the acceptance of the implant by the host. While in most situations the particles are of random size and configuration, but within the constraints of size indicated, it is generally desirable that the

particles be of generally uniform configuration for use in a given procedure. With respect to relative resilience of the augmentation mass, it is preferably designed to closely simulate the tissue of the implant or injection site.

5        For soft tissue, a soft elastomer such as silicone rubber is a desirable material for the textured particles. This is preferably a poly(dimethylsiloxane) but may have substitute alkyl or aromatic groups. When a firm area is being treated, such as connective tissue or the like, polytetrafluoroethylene (Teflon) or  
10       polyethylene may be satisfactorily utilized. In those instances wherein the requirement is for hard substances, biocompatible materials such as certain calcium salts including hydroxyapatite or other such crystalline materials, biocompatible ceramics, biocompatible metals such as certain stainless steel particles, or  
15       glass may be utilized.

By way of further background, the average diameter of a capillary is approximately 16 microns, or roughly two times the diameter of a red cell. Therefore, since the size of the textured  
20       micro particles is in the area of at least approximately 30 microns, they will not be absorbed into the capillaries, but will on the other hand, remain generally captive and fixed in place. Smaller particles, including some in the sub-micron range, have been implicated in causing chronic inflammation and may be ingested by host cells. Thus, particles in the range of between about 30  
25       and 3000 microns are employed.

B  
L  
5 The fibroblast cell is the scar-forming cell of the human body, and these cells range in size from between about 20 microns up to about 100 microns, and because of contact guidance and reduced micromotion, they will form an efficient scar tissue or collagen-based coating around an inert foreign body. Furthermore, such scar tissue will conform to the irregularities in the surface of the foreign body, particularly if they are of sufficient size to accommodate tissue ingrowth. Our previous studies (American Society of Artificial Internal Organs; U. S. Patent Nos. 3,638,649; 3,657,744; 4,239,492; and 4,240,794) have shown that foreign substances can be substantially firmly anchored in a predetermined location in the body. Because of the inherent ability of fibroblasts to form scar tissue in and around irregularities of the surface, such anchoring occurs in many locations, including  
15 locations within the blood stream.

F B  
L 10 Figure 1 illustrates a micro-implant particle generally designated 10 which has an inner-core having various randomly distributed indentations or pores 11-11 throughout its surface. These openings or pores are spaced apart by connective pillar members 12. As indicated above, the indentations, interstices or pores preferably have a minimum indentation depth or open dimension of about 10 Angstroms, along with a maximum dimension of about 500 microns. The interconnective or pillar zones 12-12 which separate or otherwise define solid material between openings or indentations  
13 11-11 have a dimension or breadth sufficient so that the majority  
13 25

or greater portion of the surface is defined by indentations, openings or pores.

B 5 Actual particles are shown in the photomicrograph of Figure 8. As can be seen from the scale of the Figure, the size range of the illustrated particles ranges from about 100 to 600 microns. The irregular particle shapes and surface configurations including indentations, openings and pores is dramatically illustrated.

10 With continued attention being directed to Figures 1 and 2 of the drawings, connective elements 12 are available on the surface of the micro-implant particles and provide for mechanical stability of the individual particle. This arrangement is illustrated in particular in Figure 2 and is apparent from the photomicrograph of Figure 8.

15 As further disclosed in the cross-referenced application, it has been found that inert foreign tissue augmentation particulate matter having a mean diameter less than about 30 microns will generally become subject to significant migratory loss from the site of injection, regardless of surface configuration absent extraordinary protection. The textured or irregular nature of the surface of the microspheres of the invention, however, imparts to them an apparent size equivalency which, in the case of at least the relatively smaller sized particles (particularly in the range of 30-60 and up to 80 microns), makes them behave, once injected, as much larger smoother particles might behave with respect to host implant or prosthesis migration tendencies and benign assimilation

B14

B  
L  
B  
L5  
in scar tissue. Particulate matter of the class of the present invention which is of a size ranging from about 30 microns to about 3000 microns and having a textured surface in which the surface irregularities vary in size over a range of about 10 Angstroms to 500 microns.

10  
The irregularities, pores and interstices are designed to have widths ranging from those having a diameter or opening size which will just accommodate the infiltration of a typical connective tissue fibril or protein molecule at the lower end to those large enough to accommodate ingrowth of much larger cross-linked protein, possibly collagen protein, fibrillar structures or actual fibroblasts at the high end. In this regard, it is well known that the collagen fiber is composed of fibrils and filaments. The basic poly-peptide chain is arranged into micro-filaments of tropocollagen having a diameter of approximately 20 Angstroms. It has been found that surface irregularities as small as 10 Angstroms will interdigitate with the filaments on the surface of the fibers and serve to resist host-prosthesis interface motion.

B 15  
L  
20  
Further, with respect to particle size, it will be appreciated that particle size, particularly of those species contained in preparations utilized in prior injectable compositions, tends to vary over a range within any group of particles so that there will be a percentage of the group larger and a percentage of the group smaller than at target size of the indentations, pores or  
25  
interstices associated with a give group of particles will also

describe a range. It will further be appreciated that one must take into account the normal variation in patient-to-patient acceptance and reaction to tissue augmentation injection of micro particles. With this in mind, certain observations have been made  
5 regarding optimum particle size, particularly with regard to the severe problems of unwanted migration and formation of granulomatous reactions.

Observations in a variety of clinical situations indicate that particles less than about 60 microns in diameter can be engulfed by  
10 macrophages and transported to regional lymph nodes. Submicron-sized particles may be the most easily transported and may remain intracellular indefinitely. However, larger particles, particles  
15 that approach the size of a macrophage, i.e., from about 20 to about 60 microns, may cause the death of a cell when engulfed. This begins a progression in which the dead cell releases its intercellular enzymes (cytokines), and those attract other phagocytes which, again, encounter and engulf the particle with the debris of the first encounter. In this manner, a vicious cycle continues on a larger scale as a chronic inflammatory response. Of  
20 course, such a response is highly undesirable.

Particles greater than about 60 microns, however, have not been observed within a cell or within lymph nodes; and, certainly,  
25 particles greater than 80 microns appear safe from initiating such foreign body reactions. Further, as in the example below, particles of an average diameter of 100 to 600 microns with

textured surfaces having an average indentation cavity or pore size  
from about 10 microns to about 200 microns have been observed to  
work quite well. Theoretically, there is no upper limit to the  
size of the textured particles, and this is borne out by the  
success of sintered-surface hip implants, textured breast implants  
and others. However, the useful upper limit of micro implant  
dimensions is probably somewhere in the vicinity of 1 to 3 mm in  
defects just beneath the skin surface because particles of a size  
greater than this may be perceived as surface irregularities when  
palpitated. Large textured implants have also been employed in  
breast reconstruction, for example.

It will be appreciated that textured spheroids of the class  
contemplated for use in the present invention may be molded, for  
example, by any gravity-free technique wherein the spheroids are  
formed with centrifugal force equal to that of gravity in cases  
where the spheroids are formed of rather malleable synthetic  
material. Spheroids can be fabricated from a variety of inert  
substances such as polytetrafluoroethylene,  
poly(methylmethacrylate), poly substituted siloxanes (silicones)  
and a variety of other synthetic polymeric materials, ceramics and  
others and different fabrication processes may be applicable to  
each material for the augmentation of soft tissue. Of course,  
fabrication of the spheroids from a malleable polymer material such  
as a silicone rubber is preferred as it will more closely imitate  
the texture of the natural tissue it replaces. With respect to

malleable polymers such as silicone rubber, the following fabrication techniques are exemplary of those that will readily enable manufacture by those skilled in the art. It will be appreciated that a technique that might be preferred for one material may not work equally well for all.

In one process, a malleable stock of unvulcanized polydimethylsiloxane is rolled into spheroids of approximately 100 microns or other desired size diameter. The surface is then textured by impacting each spheroid with an appropriate force. The textured spheroids are then vulcanized and mixed with the appropriate vehicle for injection.

In another successful method, generally preferred for forming beads of silicone rubbers, poly(di-substituted siloxane) may be dispersed in an appropriate volatile solvent and then partially cured by droplets being forced through a specific distance of air from an orifice having a specific diameter. This is a very familiar process technique generally known with respect to the operation of a shot tower in making lead shot. The size of the particles or spheroids is easily regulated by varying the viscosity of the mixture and/or the orifice of origin. As the particle travels a known distance through air, it is partially cured as the volatile vehicle evaporates. The specifically formed spheroid or bead is then separated by a suitable fluid medium. The spheroids may then be pressed against an appropriate surface or impacted by an appropriate force to impart the desired texture, the surface

having an appropriate mold release. Partially cured spheroids are then vulcanized by heat irradiation. The particles are then sized and graded by physical means. Spheroids are then mixed with the appropriate vehicle in appropriate ratios, placed in containers and finally sterilized within the container.

Texture can be imparted to the beads or spheroids in a number of ways. In addition to the molding method, other techniques include ion-beam microtexturing which makes it possible to produce controlled microtextured surfaces, chemical and plasma etching and impacting the beads with solid particles. Of course, it is contemplated that other methods could also occur to those skilled in the art.

If desired, surface modifiers, as explained above, can be incorporated in the material prior to formation of the spheroids or beads or may be thereafter be added as a coating on the deformed surfaces. In this manner, certain materials such as hyaluronic acid, for example, may be attached to the micro particle surface either through physical or chemical bonding in a well-known manner after formation and texturing.

EXAMPLE I

Amounts of particles with average diameters of 100, 150 and 600 micrometers were fabricated with a textured surface from fully polymerized and vulcanized poly(dimethylsiloxane). The polymer was mixed to form a biocompatible solution with an organic polymer hydrogel. The hydrogel was a polyvinylpyrrolidone gel having an

average molecular weight of approximately 13,700 and one of a family of such material known as Plasdone. These Plasdone in a molecular weight range of interest are freely transported through tissue fluids and excreted unchanged by the kidneys. The mixture utilized was approximately 38% by weight of the polymer particles and 62% of the gel material. The polymer/gel mixture was mixed until the inert particles were evenly dispersed and then placed in syringes with small pistons placed in the proximal ends. The distal end of each cylinder would have a Luer taper to which an appropriate needle or cannula could be attached. A highly leveraged injection ratchet mechanism was utilized to accept the syringe cartridges and deliver precise amounts of the gel mixture through a cannula into the subcutaneous plane of the ear tissue of 20 large, adult white rabbits. Controls using commercially available collagen derivatives were injected in the subcutaneous plane in adjacent sites in the rabbits' ears using small gauge needles provided by the manufacturers of the collagen derivatives.

With respect to the injected collagen control sites, subsequent histologic sections indicated that after three weeks, no residual collagen could be found at the site of the injection. In dramatic contrast, the histologic sections of the micro particles evidenced a dramatic transition in which the gel phase of the material was replaced by a fibrin and protocollagen matrix surrounding each of the micro particles. In three days, the fibrin matrix was complete, with all the gel having been removed by the

host. Connective-tissue cells had developed and had begun to replace the matrix with host collagen fibrils. By the sixth week, this fibrosis was complete, and each individual textured particle appeared to be encased in its own individual inner connected covering of fibrous tissue. The thickness of the implanted area and the degree of fibrosis as measured by transillumination, micrometer and light and electron beam microscopy remained constant for more than a year.

Subsequent histologic examination of the regional lymph nodes at the base of the rabbit ears revealed no migration of particles. Cross-sections of the ear below the injected area showed no particles. Through transillumination, the size and density of the areas of injection were easily and atraumatically monitored for each rabbit. No textured micro implants were found at the base of the ears or in the regional lymph nodes of any of the rabbits under study.

The dimensions of the subcutaneous deposits of textured micro implants remained approximately the same throughout the period of study, as was evidenced by transillumination photographic record and micrometer measurement. Opacity was noted to decrease over the last few weeks as the transillumination became brighter but then appeared to stabilize between the end of the first and the sixth months.

The results obtained with the experimental particles of Example 1 illustrate the dramatic contrast between this material

13 B  
L  
B 5  
L  
and the injection of collagen-containing materials. Although the collagen-containing materials created immediate soft tissue augmentation, these substances - which are only about 3.5 to 6.5% solid collagen material - soon became invaded by host capillaries and were absorbed. No absorption or migration of the 100, 150 or 600 micron silicone rubber particles was observed, even after 382 days.

B  
10  
In other experiments, particles having an average diameter of 80 microns and incorporating tracer material in the form of gamma radiation-emitting material were injected into the ears of other rabbits. These particles showed no migration from the injection site during a subsequent six-month monitoring period.

B  
15  
While prior work by the inventors and others have shown that surface irregularities preferably are in the 20 to 200 micron range in order to achieve adequate contact guidance of the fibroblasts so as to create or develop a scar tissue pattern that is a mirror image of the substrate surface, it is also appreciated that the particle size in relation to the relative size of the surface irregularities is a factor to be considered. In this connection,  
20  
if the openings, indentations or pores are too shallow in their depth dimension, or in the event their diameter is not sufficiently great, the fibroblasts will tend to bridge across the defect so as to provide a substantially smooth surface.

25  
In the preferred embodiment of the present invention, the particles indicated or selected for a specific procedure to assist

in correcting a given defect are previously loaded into a hypodermic syringe with a needle having an adequately sized interior bore so that upon injection of the needle into the area of the depression being corrected, the particles together with the appropriate physiologic vehicle enables the spheroids to be injected directly into the area of the depression. Appropriate vehicles, as previously indicated, include physiologic saline or polysaccharide lubricants, each of these enabling the spheroids to be injected as set forth.

With attention being directed to Figure 3 of the drawings, it will be noted that surface tissue as shown at 20 includes a depression area 21, with the depression area extending into the subcutaneous tissue as at 22. For utilization of the concept of the present invention, the needle 23 is shown as it is injected into tissue. Particles 30, of the type illustrated in Figures 1 and 2, along with vehicle 31 are injected into the predetermined site, with the result being filling of the depression area, particularly as illustrated in Figure 4. Upon withdrawal of the needle 23, the injected material is left in situ at the selected site. The supply of particles 30 is retained in syringe body zone 23A for passage through hollow needle 23.

As further illustrated in Figure 7, the needle 23 may be provided with a marker as at 50, which may be any desired color, to indicate the depth of tissue penetration so that the precise

relative location of the needle bevel relative to a bladder neck  
51, for example, may be gauged without fluoroscopy.

Syringes of this type are, of course, commercially available,  
and suitable for particles in the low to mid-size range, while  
5 larger particles within the size range may require an inwardly  
tapered out-flow tract. For certain applications, it has been  
found desirable to utilize a syringe-needle combination which  
tapers continuously, thereby providing an elongated syringe-needle  
combination with a inwardly tapered out-flow tract.

10 Generally, upon completion of the inflammatory phase of wound  
healing, or after approximately one week, formation of scar tissue  
commences with this becoming complete after about three weeks.  
Following completion of the deposition and formation of scar  
tissue, a remodeling phase or operation may be undertaken. In view  
15 of the specific irregularities and indentations of the surfaces of  
the individual particles, contact guidance will normally allow for  
the resulting scar tissue to firmly anchor and attach the implanted  
particles 30 wherever deposited. As borne out by the example,  
although various biological substances have been used for similar  
20 purposes, such as collagen and fibril, these other previously  
utilized substances are normally broken down by the body over a  
period of time and digested autogenously.

It is anticipated that the micro particles fabricated of  
silicone rubber, polytetrafluoroethylene (Teflon), ceramic or other  
25 appropriate inert substances will mimic the durometer hardness of

the host tissue being filled, with the softer materials, such as silicone rubber being utilized for normal subcutaneous fat tissue, and with ceramic materials being utilized for bone tissue. Polytetrafluoroethylene (Teflon) is deemed suitable for cartilage, and silicone elastomer with variations in firmness for subcutaneous fat in various regions of the body. In the event the procedure involves an over-correction, the use of lipoplasty techniques of suction lipectomy with a cannula of appropriate diameter will allow for fine tuning, even after several months or years. Removal of an appropriate quantity of filler material may be accomplished in that fashion.

Specific attention is now directed to the modification of particle configuration illustrated in Figures 5 and 6. Specifically, the textured micro particle generally designated 40 comprises a central body portion 41 of generally spheroidal form, together with a number of outwardly projecting pillar members 42-42 thereon. Inter-pillar indentations of generally arcuate form are shown at 43-43. Textured micro particles of the type illustrated in Figures 5 and 6 may also be found useful in connection with the various aspects of the present invention. In actual use, these micro particles will be combined with an appropriate vehicle, of the type previously referred to, such as physiologic saline, PVP or polysaccharide lubricant, so as to enable these textured micro particles to be injected into the body. Also, textured micro particles of the type illustrated in Figures 5 and 6 may be formed

14 of the same material as indicated in connection with the embodiment  
of Figures 1-4, such as for example, silicone rubber,  
polytetrafluoroethylene (Teflon), biocompatible solids such as, for  
example, hydroxyapatite or other biocompatible solids of the type  
5 listed hereinabove.

Radiopaque substances such as, for example, barium compounds,  
may be utilized to make the particles more visible. Radioactive  
materials may also be incorporated for certain applications. In  
most instances, however, utilization of such radiographic tagging  
10 will not be required.

The foregoing detailed description has been provided directed  
to the micro particles contemplated in the practice of the present  
invention to render the instant specification complete in and of  
itself, without the need for incorporation by reference and/or  
15 resort to the cross-referenced application.

As was previously stated, the essence of the present invention  
is to provide novel procedures for treating urological disorders,  
particularly stress incontinence and ureteral reflux, wherein  
textured micro particles of the foregoing description in a  
20 biocompatible liquid vehicle are injected endoscopically into  
submucosal tissue in order to add bulk.

In accordance with the present invention, stress incontinence  
may be treated by a plurality of spaced injections of the  
aforementioned micro particles into the submucosal space of the  
25 urethra in order to provide the necessary bulk. The amount of the

micro particles to be injected will depend at least in part upon the amount of bulk desired for the particular procedure. Accordingly, it is not capable of precise quantification. For this reason, the amount to be injected may be referred to as an  
5 "effective amount", meaning an amount effective to provide the desired result. By way of illustration, an "effective amount" in the treatment of stress incontinence is the amount needed to provide the necessary bulk to elevate the mucosa a predetermined  
10 desired distance, e.g., on the order of about 2.0 cm.

The procedure, which may be performed under local, regional or general anesthesia, is performed so as to provide a series of  
15 mounds which usually include the urethral lumen. The micro particles to be implanted are combined with a biocompatible polymer liquid carrier or vehicle in order to permit the contemplated micro-implant surgery to be accomplished by endoscopic injection.

Thus, according to the present invention, soft tissue augmentation may be obtained by direct cannula injection surgery. Following implantation in the desired submucosa site(s), the micro particle/liquid vehicle combination will undergo a transformation  
20 whereby the liquid vehicle component is rapidly scavenged by the host inflammatory cells and then replaced by host fibrin. In this manner, all of the liquid vehicle carrier phase is dispersed by the mammalian host and then completely excreted by the kidneys within a few days. In vivo studies of both animals and humans reported in  
25 the literature have shown that massive amounts of the liquid

carrier injected intravenously or subcutaneously are promptly excreted from the body chemically unaltered. Examples of these are as follows: Rhodes, J.E.: "Various plasma expanders in man."

I B5 14 J.: ANNUAL, NEW YORK ACADEMY OF SCIENCE, 55:522-525, 1952; Harwicke, K. & Honda, K.: Advances in Nephrology. 2:61-74, 1972; Kojima, M., Takahashi, K. & Honda, K.: "Morphological study on the effect of polyvinylpyrrolidone infusion upon the reticuloendothelial system." VLI B14  
TOKYO J. EXP. MED., 92:27-54, 1967."

10 The transformation of the injected substances into specific individual micro-implant particles, each encased in a host collagen lattice occurs in an orderly step-by-step fashion over a relatively short period of time, e.g., over on the order of several weeks. First, as previously stated, the liquid vehicle is replaced by fibrin. Then, the host fibrin is replaced by connective tissue  
15 cells which deposit collagen between and through the textured particles.

The following example shows by way of illustration and not by way of limitation procedures steps for treating stress incontinence in accordance with this invention.

EXAMPLE 2

The micro particles/liquid vehicle composition to be injected comprised textured poly(dimethylsiloxane) micro particles ranging generally from about 100-600 micrometers mixed with a PVP gel to provide a biocompatible biphasic solution as described in

B  
Example 1. In the following procedure, this solution was contained in a syringe mounted in a pressure injection gun.

P1 B  
1. As desired, local, regional or general anesthesia is administered.

P1 B 5  
2. The patient is positioned in the lithotomy position.

P1 B  
3. A cystoscope equipped with a panendoscopic lens is inserted into the urethra and the urethra then examined for the suitability of submucosal injection.

P1 10B, 3  
4. Assuming suitability, the patient's bladder is then filled with sterile water from on the order of one-fourth to one-half full.

P1 B  
15  
5. A long 16-gauge needle with a cuff one centimeter from the end is passed into the cystoscope or it may be inserted outside the urethra, through the peritoneum, into the region of the bladder neck. The needle is guided by palpitation and visual control through the scope. The syringe mounted in the pressure injection gun and containing the micro particle solution to be injected is attached to the proximal end of the needle.

P1 B, 3  
20  
6. The needle is advanced to the six o'clock position and inserted (bevel up) into the submucosal space, approximately 1-3 cm caudad to the bladder neck, as illustrated in Figure 7.

P1 B  
7. The position of the needle is checked by inserting a small amount of the micro particle solution. If the needle is properly placed, a bump will appear immediately in the submucosa.

P1 5 B  
L  
B  
10 B  
L14  
8. If the injection site is correct, approximately 1.0 to 5.0 cc will generally be required per injection site. The injection should elevate the mucosa for a distance of about 2.0 cm. In making the injection, the needle should be held in place for about 30 seconds. The needle is then backed away from the injected material approximately 0.5 cm for 20-20 seconds after the injection is completed in order to seal the injection site.

P1 B  
15 L3  
B.3  
9. The injection is then repeated at each of the 3 o'clock and 9 o'clock positions and, if necessary, at the 12 o'clock position.

P  
As heretofore mentioned, the final result should be a series of mounds which visually occlude the urethral lumen. This allows the patient to gain needed closure control.

20 While the invention is particularly directed to the treatment of stress incontinence, it is expressly to be understood that it may also be employed for treatment of other urological disorders by injection of the aforementioned texture micro particle solution. By way of further illustration, it may for example be employed in  
25 the correction of vesicoureteral reflux which has heretofore been

1 treated by endoscope injection of polytetrafluoroethylene paste  
2 under the intravesical portion of the affected ureter. This is  
3 described in, for example, "TECHNICAL REFINEMENTS IN ENDOSCOPIC  
4 CORRECTION OF VESICoureTERAL REFLUX", by O'Donnel and Puri, The  
5 Journal of Urology, vol. 140, November, 1988, pp. 1101-1102.

6 In accordance with the present invention, endoscopic injection  
7 may be made in the same manner as that described in the above-  
8 mentioned Urology Journal, substituting applicants' novel textured  
9 micro particle solution for the polytetrafluoropolyethylene parts  
10 hereto employed. For example, with the patient positioned with the  
11 thighs extended and fully abducted to flatten the case of the  
12 bladder,

13 Insert the needle bevel upwards into about 6 to 10 mm, of  
14 the submucosa (lamina propria) at exactly the 6 o'clock  
15 position and 5 mm. should be under the ureter itself.  
16 after the needle is in place but before injection lift  
17 the needle gently under the ureter so that one can  
18 outline exactly the position of the point of the needle.  
19 It is important not to inject the paste into the muscle  
20 of the bladder and not to perforate the ureter.  
21 Injection should be done slowly and the effect of each  
22 increment should be visualized. The paste is injected  
23 until a nipple is created by the paste on top of which  
24 sits the now flattened ureteral orifice like an inverted  
25 crescent. The volume of paste required varies with the

condition of the orifice and the age of the patient. The  
needle is kept in position for about 30 seconds after  
injection to avoid extrusion . . . .

As further described in this article, the needle hole may then be  
irrigated to remove any loose particles of paste.

In general it can be said that the present invention is  
applicable to the correction of the various urological disorders  
heretofore treated by endoscopic injection of particles to fill  
defects and/or provide bulk. Treatment of other urological  
disorders are also contemplated by the present invention. For  
example, the treatment of post-prostatectomy incontinence and  
incontinence of females associated with cystourethroceles by  
intraurethral injection of polytetrafluoroethylene particles is  
known. (See, for example, "PERIURETHRAL POLYTETRAFLUOROETHYLENE  
INJECTION FOR URINARY INCONTINENCE", by Politano, The Journal of  
Urology, vol. 127, March, 1982, pp. 439-442.)

This invention has been described herein in considerable  
detail in order to comply with the Patent Statutes and to provide  
those skilled in the art with the information needed to apply the  
novel principles and to construct and use such specialized  
components as are required. However, it is to be understood that  
the invention can be carried out by specifically different  
equipment and devices, and that various modifications, both as to  
the equipment details and operating procedures, can be accomplished  
without departing from the scope of the invention itself.
